²Schlumberger Research Cambridge, Cambridge, UK London

Motivation: Why degradation matters

Starting point: Process level MI(N)LP model

$$\begin{array}{ll} \min_{\boldsymbol{x}, \boldsymbol{m}} & \text{cost}(\boldsymbol{x}, \boldsymbol{m}) \\ \text{s.t.} & \text{process model}(\boldsymbol{x}, \boldsymbol{m}) \quad (\text{eg. balance equations}) \\ & \text{maintenance model}(\boldsymbol{x}, \boldsymbol{m}) \quad (\text{eg. types of maint.}) \end{array}$$

where \boldsymbol{x} are process variables, \boldsymbol{m} are maintenance variables

Starting point: Process level MI(N)LP model

$$\begin{array}{ll} \min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} & \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ \text{s.t.} & \text{process model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \quad (\text{eg. balance equations}) \\ & \text{maintenance model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \quad (\text{eg. types of maint.}) \\ & \text{health model}(\mathbf{x}, \mathbf{m}, \mathbf{h}), \quad (\text{eq. prognosis model}) \end{array}$$

where \mathbf{x} are process variables, \mathbf{m} are maintenance variables, and \mathbf{h} are health related variables.

Starting point: Process level MI(N)LP model

$$\begin{array}{ll} \min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} & \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ \text{s.t.} & \text{process model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \quad (\text{eg. balance equations}) \\ & \text{maintenance model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \quad (\text{eg. types of maint.}) \\ & \text{health model}(\mathbf{x}, \mathbf{m}, \mathbf{h}), \quad (\text{eq. prognosis model}) \end{array}$$

where \mathbf{x} are process variables, \mathbf{m} are maintenance variables, and \mathbf{h} are health related variables.

Related Work

Vassiliads and Pistikopoulos (2001); Liu, Yahia and Papageorgiou (2014); Xenos, et al., Thornhill (2016); Aguirre and Papageorgiou (2018); Biondi, Sand and Harjunkoski (2017); Yildirim, Gebraeel and Sun (2017); Başçiftci, Ahmed, Gebraeel and Yildirim (2018)

Starting point: Process level MI(N)LP model

$$\begin{aligned} \min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} \quad & \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ \text{s.t.} \quad & \text{process model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) && (\text{eg. balance equations}) \\ & \text{maintenance model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) && (\text{eg. types of maint.}) \\ & \text{health model}(\mathbf{x}, \mathbf{m}, \mathbf{h}), && (\text{eq. prognosis model}) \end{aligned}$$

where \mathbf{x} are process variables, \mathbf{m} are maintenance variables, and \mathbf{h} are health related variables.

Idea

Combine process level MI(N)LP scheduling & planning with more sophisticated (stochastic) degradation modelling and robust optimization.

What is degradation modelling?

What is degradation modelling?

The degradation signal $s^{meas}(t)$ can be modelled by a stochastic process :

$$S(t) = \{S_t : t \in T\},$$

where S_t is a random variable (Alaswad and Xiang, 2017).

What is degradation modelling?

The degradation signal $s^{meas}(t)$ can be modelled by a stochastic process :

$$S(t) = \{S_t : t \in T\},$$

where S_t is a random variable (Alaswad and Xiang, 2017).

Often used: Lévy type processes (Applebaum, 2004)

- Independent increments: $S_{t_2} - S_{t_1}, \dots, S_{t_n} - S_{t_{n-1}}$ are independent for any $0 < t_1 < t_2 < \dots < t_n < \infty$
- Stationary increments: $S_t - S_s$ and S_{t-s} have the same distribution for any $s < t$

What is degradation modelling?

The degradation signal $s^{meas}(t)$ can be modelled by a stochastic process :

$$S(t) = \{S_t : t \in T\},$$

where S_t is a random variable (Alaswad and Xiang, 2017).

Often used: Lévy type processes (Applebaum, 2004)

- Independent increments: $S_{t_2} - S_{t_1}, \dots, S_{t_n} - S_{t_{n-1}}$ are independent for any $0 < t_1 < t_2 < \dots < t_n < \infty$
- Stationary increments: $S_t - S_s$ and S_{t-s} have the same distribution for any $s < t$

Therefore $S_t - S_{t-\Delta t} = D \sim \mathcal{D}(\Theta, \Delta t)$, where Θ are parameters of distribution \mathcal{D} .

What is degradation modelling?

A health model based on Lévy processes

Assumption

The health of each unit j can be described by a Lévy process $S_j(t)$ with increments $S_{j,t} - S_{j,t-\Delta t} = D_j \sim \mathcal{D}_j(\Theta, \Delta t)$.

A health model based on Lévy processes

Assumption

The health of each unit j can be described by a Lévy process $S_j(t)$ with increments $S_{j,t} - S_{j,t-\Delta t} = D_j \sim \mathcal{D}_j(\Theta, \Delta t)$.

$$\begin{aligned} \min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} \quad & \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ \text{s.t.} \quad & \text{process model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ & \text{maintenance model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ & S_{j,t} \leq s_j^{\max} \quad \forall t, j \in J \\ & S_{j,t} = \begin{cases} S_{j,t-1} + D_j, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} \quad \forall t, j \in J \end{aligned}$$

where $m_{j,t} = 1$ if maintenance is performed on unit j at time t .

A health model based on Lévy processes

Assumption (Liao and Tian, 2013)

All relevant operating variables are piecewise constant – i.e. the process has a set of discrete operating modes $k \in K$.

Accounting for effects of process variables

Assumption (Liao and Tian, 2013)

All relevant operating variables are piecewise constant – i.e. the process has a set of discrete operating modes $k \in K$.

$$\begin{aligned} \min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} \quad & \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ \text{s.t.} \quad & \text{process model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ & \text{maintenance model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ & S_{j,t} \leq s_j^{\max} \quad \forall t, j \in J \\ & S_{j,t} = \begin{cases} S_{j,t-1} + \sum_{k \in K} x_{j,k,t} \cdot D_{j,k}, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} \quad \forall t, j \in J \end{aligned}$$

where $x_{j,k,t} = 1$ if unit j operates in mode k at time t .

Deriving a robust counterpart (Lappas and Gounaris, 2016)

Idea

Replace random variables $D_{j,k}$ and $S_{j,t}$ by uncertain parameter $\tilde{d}_{j,k} \in \mathcal{U}$ and second stage variable $s_{j,t}(\tilde{d}_{j,k})$.

$$\min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} \quad \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h})$$

$$\text{s.t.} \quad \text{process model}(\mathbf{x}, \mathbf{m}, \mathbf{h})$$

$$\text{maintenance model}(\mathbf{x}, \mathbf{m}, \mathbf{h})$$

$$s_{j,t}(\tilde{d}_{j,k}) \leq s_j^{\max} \quad \forall t, j \in J$$

$$s_{j,t} = \begin{cases} s_{j,t-1} + \sum_{k \in \mathcal{K}} x_{j,k,t} \cdot \tilde{d}_{j,k}, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} \quad \forall t, j \in J$$

$$\forall \tilde{d}_{j,k} \in \mathcal{U}.$$

Deriving a robust counterpart (Lappas and Gounaris, 2016)

Idea

Replace random variables $D_{j,k}$ and $S_{j,t}$ by uncertain parameter $\tilde{d}_{j,k} \in \mathcal{U}$ and second stage variable $s_{j,t}(\tilde{d}_{j,k})$.

$$\min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} \quad \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h})$$

$$\text{s.t.} \quad \text{process model}(\mathbf{x}, \mathbf{m}, \mathbf{h})$$

$$\text{maintenance model}(\mathbf{x}, \mathbf{m}, \mathbf{h})$$

$$s_{j,t}(\tilde{d}_{j,k}) \leq s_j^{\max} \quad \forall t, j \in J$$

$$s_{j,t} = \begin{cases} s_{j,t-1} + \sum_{k \in \mathcal{K}} x_{j,k,t} \tilde{d}_{j,k}, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} \quad \forall t, j \in J$$

$\forall \tilde{d}_{j,k} \in \mathcal{U}$. Approximate $s_{j,t}(\tilde{d}_{j,k})$ by linear decision rule. Utilize Robust Optimization reformulation techniques.

How do we choose \mathcal{U} ?

Assumption: \mathcal{U} is a box uncertainty set

$$\mathcal{U} = \{\tilde{d}_{j,k} | \bar{d}_{j,k}(1 - \epsilon_{j,k}) \leq \tilde{d}_{j,k} \leq \bar{d}_{j,k}(1 + \epsilon_{j,k})\}$$

How do we choose \mathcal{U} ?

Assumption: \mathcal{U} is a box uncertainty set

$$\mathcal{U} = \{\tilde{d}_{j,k} | \bar{d}_{j,k}(1 - \epsilon_{j,k}) \leq \tilde{d}_{j,k} \leq \bar{d}_{j,k}(1 + \epsilon_{j,k})\}$$

Choose $\epsilon_{j,k}$ from distribution $\mathcal{D}_{j,k}$:

$$\epsilon_{j,k} = 1 - F^{-1}(\alpha) / \bar{d}_{j,k}$$

Size of \mathcal{U} depends on a single parameter α !

Case study: State-Task-Network (Kondili et al., 1993)

Case study: State-Task-Network (Kondili et al., 1993)

Biondi, Sand and Harjunkski (2017) extend the STN to include...

- ...unit health and maintenance scheduling
- ...integrated scheduling and planning
- ...multiple operating modes per task

Case study: State-Task-Network (Kondili et al., 1993)

This work...

- ...replaces their deterministic health model by the proposed approach based on degradation modelling.
- ...utilizes robust optimization to obtain a solution that is likely to remain feasible.

Evaluating solution robustness

The price of robustness

Choosing α is its own optimization problem

We optimize α by solving

$$\min_{\alpha} c^*(\alpha) + \sum_j p_j^f(\alpha) \cdot c_j^f$$

- $c^*(\alpha)$ is the objective value of a MILP solution given α .
- $p_j^f(\alpha)$ is the corresponding probability of failure (of unit j).
- c_j^f is the cost of an unexpected failure.

Choosing α is its own optimization problem

We optimize α by solving

$$\min_{\alpha} c^*(\alpha) + \sum_j p_j^f(\alpha) \cdot c_j^f$$

- $c^*(\alpha)$ is the objective value of a MILP solution given α .
- $p_j^f(\alpha)$ is the corresponding probability of failure (of unit j).
- c_j^f is the cost of an unexpected failure.

Idea: Use Bayesian Optimization (BO)

Both c^* and p_j^f can be viewed as expensive black box functions. BO is very suitable for this setting (Jones et al., 1998).

Saving time: a deterministic approximation

Assumption

Only the health model depends on $\tilde{d}_{j,k}$ and $\tilde{d}_{j,k} \geq 0$.

Then we can prove that a solution to

$$\begin{aligned} \min_{\mathbf{x}, \mathbf{m}, \mathbf{h}} \quad & \text{cost}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ \text{s.t.} \quad & \text{process model, maint. model}(\mathbf{x}, \mathbf{m}, \mathbf{h}) \\ & s_{j,t} \leq s_j^{\max} \quad \forall t, j \in J \\ & s_{j,t} = \begin{cases} s_{j,t-1} + \sum_{k \in \mathcal{K}} x_{j,k,t} \cdot d_{j,k}^{\max}, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} \quad \forall t, j \in J \end{aligned}$$

with $d_{j,k}^{\max} = \max_{\mathcal{U}} \tilde{d}_{j,k}$ is also feasible in the robust problem.

Saving time: a deterministic approximation

Saving time: data-driven approximations

An upper bound on the probability of failure p_j^f can be estimated from data (using logistic regression).

Estimate from data:

Saving time: data-driven approximations

Bayesian Optimization

Bayesian Optimization

Degradation modelling

Degradation modelling with multiple operating modes

How does robust optimization work?

General idea

- Make constraints hold for all values in \mathcal{U} : $\sum_j \tilde{a}_{ij} x_j \leq b_i, \forall \tilde{a}_{ij} \in \mathcal{U}$
- Reformulate semi-infinite constraint:
$$\sum_j a_{ij} x_j + \text{protection}(\mathcal{U}) \leq b_i$$
- How do we choose the right protection level?

Example: Soyster's method (worst case) [1973]

$$\max_{x_1, x_2} \quad x_1 + x_2$$

$$\text{s.t.} \quad \tilde{a}_{11} x_1 + \tilde{a}_{12} x_2 \leq b_1, \\ \forall \tilde{a}_{ij} \in \mathcal{U}$$

$$\max_{x_1, x_2} \quad x_1 + x_2$$

$$\text{s.t.} \quad a_{11} x_1 + a_{12} x_2 + \sum_j \hat{a}_{ij} |x_j| \leq b_1$$

$$\text{Given: } [a_{11}, a_{12}] = [1, 2], [\hat{a}_{11}, \hat{a}_{12}] = [0.1, 0.2], [b_1] = [2]$$

Formulation

Scheduling

$$M_{j,t} S_{j,0} \leq S_{j,t} \leq S_{j,max} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \quad \forall t, j \in J, D \in \mathcal{D}$$

$$S_{j,t} \geq S_{j,t-\Delta t} + \sum_k Z_{j,k,t} D_{j,k,t} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \quad \forall t, j \in J, D \in \mathcal{D}$$

$$S_{j,t} \leq S_{j,t-\Delta t} + \sum_k Z_{j,k,t} D_{j,k,t} \quad \forall t, j \in J, D \in \mathcal{D}$$

Planning

$$S_{j,t} \leq S_{j,max} \quad \forall t, j \in J$$

$$S_{j,t} \geq S_{j,t-\Delta t} + \sum_k N_{j,k,t} D_{j,k,t} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \quad \forall t, j \in J$$

$$S_{j,t} \leq S_{j,t-\Delta t} + \sum_k N_{j,k,t} D_{j,k,t} \quad \forall t, j \in J$$

Adjustable robust optimization

Affine decision rule

$$S_{j,t} = [S_{j,t}]_0 + \sum_k \sum_{t'=0}^t [S_{j,t}]_{k,t'} D_{j,k,t'}. \quad (1)$$

Deriving a robust counterpart

Replace $D_{j,k}$ by an uncertain parameter $\tilde{d}_{j,k}$ bounded by a set \mathcal{U} :

$$\begin{aligned} s_{j,t} &\leq s_j^{max} & \forall t, j \in J \\ s_{j,t} &= \begin{cases} s_{j,t-1} + \sum_{k \in \mathcal{K}} x_{j,k,t} \cdot \tilde{d}_{j,k}, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} & \forall \tilde{d}_{j,k} \in \mathcal{U}, t, j \in J \end{aligned}$$

Reformulate:

$$\begin{aligned} m_{j,t} s_j^0 &\leq s_{j,t} \leq s_j^{max} + m_{j,t} \cdot (s_j^0 - s_{j,max}) & \forall t, j \in J, \tilde{d}_{j,k} \in \mathcal{U} \\ s_{j,t} &\geq s_{j,t-\Delta t} + \sum_k x_{j,k,t} \tilde{d}_{j,k} + m_{j,t} \cdot (s_j^0 - s_j^{max}) & \forall t, j \in J, \tilde{d}_{j,k} \in \mathcal{U} \\ s_{j,t} &\leq s_{j,t-\Delta t} + \sum_k x_{j,k,t} \tilde{d}_{j,k} & \forall t, j \in J, \tilde{d}_{j,k} \in \mathcal{U}, \end{aligned}$$

Replace $s_{j,t}$ by linear decision rule $s_{j,t} = [s_{j,t}]_0 + \sum_k [s_{j,t}]_k \tilde{d}_{j,k}$.
