## Data-driven optimization of processes with degrading equipment

Johannes Wiebe<sup>1</sup>, Inês Cecílio<sup>2</sup>, Ruth Misener<sup>1</sup> Wednesday 1<sup>st</sup> August, 2018

<sup>&</sup>lt;sup>1</sup>Department of Computing, Imperial College London, London, UK

<sup>&</sup>lt;sup>2</sup>Schlumberger Research Cambridge, Cambridge, UK London

## Motivation: Why degradation matters

```
\begin{array}{ccc} \min & \cos(\boldsymbol{x}, \boldsymbol{m} &) \\ \text{s.t.} & \operatorname{process} \operatorname{model}(\boldsymbol{x}, \boldsymbol{m} &) & \text{(eg. balance equations)} \\ & & \operatorname{maintenance} \operatorname{model}(\boldsymbol{x}, \boldsymbol{m} &) & \text{(eg. types of maint.)} \end{array}
```

where  $\boldsymbol{x}$  are process variables,  $\boldsymbol{m}$  are maintenance variables

```
\begin{array}{ll} \min \limits_{\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}} & \operatorname{cost}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \\ \text{s.t.} & \operatorname{process\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & (\text{eg. balance\ equations}) \\ & \operatorname{maintenance\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & (\text{eg. types\ of\ maint.}) \\ & \operatorname{health\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}), & (\text{eq. prognosis\ model}) \end{array}
```

where x are process variables, m are maintenance variables, and h are health related variables.

```
\begin{array}{ll} \min\limits_{\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}} & \mathrm{cost}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \\ \mathrm{s.t.} & \mathrm{process\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & \mathrm{(eg.\ balance\ equations)} \\ & & \mathrm{maintenance\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & \mathrm{(eg.\ types\ of\ maint.)} \\ & & \mathrm{health\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}), & \mathrm{(eq.\ prognosis\ model)} \end{array}
```

where x are process variables, m are maintenance variables, and h are health related variables.

#### **Related Work**

```
\begin{array}{ll} \min \limits_{\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}} & \operatorname{cost}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \\ \text{s.t.} & \operatorname{process\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & (\text{eg. balance\ equations}) \\ & \operatorname{maintenance\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & (\text{eg. types\ of\ maint.}) \\ & \operatorname{health\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}), & (\text{eq. prognosis\ model}) \end{array}
```

where x are process variables, m are maintenance variables, and h are health related variables.

#### Idea

Combine process level MI(N)LP scheduling & planning with more sophisticated (stochastic) degradation modelling and robust optimization.

The degradation signal  $s^{meas}(t)$  can be modelled by a stochastic process :

$$S(t) = \{S_t : t \in T\},\$$

where  $S_t$  is a random variable (Alaswad and Xiang, 2017).

The degradation signal  $s^{meas}(t)$  can be modelled by a stochastic process :

$$S(t) = \{S_t : t \in T\},\$$

where  $S_t$  is a random variable (Alaswad and Xiang, 2017).

## Often used: Lévy type processes (Applebaum, 2004)

- · Independent increments:  $S_{t_2} S_{t_1}, ..., S_{t_n} S_{t_{n-1}}$  are independent for any  $0 < t_1 < t_2 < ... < t_n < \infty$
- Stationary increments:  $S_t S_s$  and  $S_{t-s}$  have the same distribution for any s < t

The degradation signal  $s^{meas}(t)$  can be modelled by a stochastic process :

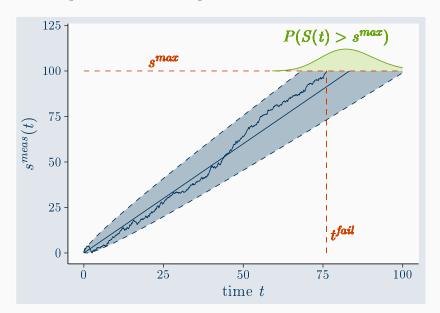

$$S(t) = \{S_t : t \in T\},\$$

where  $S_t$  is a random variable (Alaswad and Xiang, 2017).

## Often used: Lévy type processes (Applebaum, 2004)

- Independent increments:  $S_{t_2} S_{t_1}, ..., S_{t_n} S_{t_{n-1}}$  are independent for any  $0 < t_1 < t_2 < ... < t_n < \infty$
- Stationary increments:  $S_t S_s$  and  $S_{t-s}$  have the same distribution for any s < t

Therefore  $S_t - S_{t-\Delta t} = D \sim \mathcal{D}(\Theta, \Delta t)$ , where  $\Theta$  are parameters of distribution  $\mathcal{D}$ .

## A health model based on Lévy processes

## Assumption

The health of each unit j can be described by a Lévy process  $S_j(t)$  with increments  $S_{j,t} - S_{j,t-\Delta t} = D_j \sim \mathcal{D}_j(\Theta, \Delta t)$ .

## A health model based on Lévy processes

## Assumption

The health of each unit j can be described by a Lévy process  $S_j(t)$  with increments  $S_{j,t} - S_{j,t-\Delta t} = D_j \sim \mathcal{D}_j(\Theta, \Delta t)$ .

$$\begin{aligned} & \underset{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}}{\min} & & \operatorname{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & \text{s.t.} & & \operatorname{process model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & \operatorname{maintenance model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & S_{j,t} \leq s_j^{max} & & \forall t, j \in J \\ & & & S_{j,t} = \begin{cases} S_{j,t-1} + D_j, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} & \forall t, j \in J \end{aligned}$$

where  $m_{j,t} = 1$  if maintenance is performed on unit j at time t.

## A health model based on Lévy processes

## Assumption (Liao and Tian, 2013)

All relevant operating variables are piecewise constant – i.e. the process has a set of discrete operating modes  $k \in K$ .

## Accounting for effects of process variables

## Assumption (Liao and Tian, 2013)

All relevant operating variables are piecewise constant – i.e. the process has a set of discrete operating modes  $k \in K$ .

where  $x_{i,k,t} = 1$  if unit j operates in mode k at time t.

## Deriving a robust counterpart (Lappas and Gounaris, 2016)

#### Idea

Replace random variables  $D_{j,k}$  and  $S_{j,t}$  by uncertain parameter  $\tilde{d}_{j,k} \in \mathcal{U}$  and second stage variable  $s_{j,t}(\tilde{d}_{j,k})$ .

$$\begin{aligned} & \min_{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}} & \operatorname{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & \text{s.t.} & \operatorname{process} & \operatorname{model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & \operatorname{maintenance} & \operatorname{model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & s_{j,t}(\tilde{\boldsymbol{d}}_{j,k}) \leq s_{j}^{max} & \forall t, j \in J \\ & s_{j,t} = \begin{cases} s_{j,t-1} + \sum\limits_{k \in \mathcal{K}} x_{j,k,t} \cdot \tilde{\boldsymbol{d}}_{j,k}, & \text{if } m_{j,t} = 0 \\ s_{j}^{0}, & \text{otherwise} \end{cases} & \forall t, j \in J \end{aligned}$$

$$\forall \tilde{d}_{j,k} \in \mathcal{U}$$
.

## Deriving a robust counterpart (Lappas and Gounaris, 2016)

#### Idea

Replace random variables  $D_{j,k}$  and  $S_{j,t}$  by uncertain parameter  $\tilde{d}_{j,k} \in \mathcal{U}$  and second stage variable  $s_{j,t}(\tilde{d}_{j,k})$ .

$$\begin{aligned} & \min_{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}} & \operatorname{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & \text{s.t.} & \operatorname{process\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & \operatorname{maintenance\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & s_{j,t}(\tilde{\boldsymbol{d}}_{j,k}) \leq s_{j}^{max} & \forall t, j \in J \\ & s_{j,t} = \begin{cases} s_{j,t-1} + \sum\limits_{k \in \mathcal{K}} x_{j,k,t} \cdot \tilde{\boldsymbol{d}}_{j,k}, & \text{if } m_{j,t} = 0 \\ s_{j}^{0}, & \text{otherwise} \end{cases} & \forall t, j \in J \end{aligned}$$

 $\forall \tilde{d}_{j,k} \in \mathcal{U}$ . Approximate  $s_{j,t}(\tilde{d}_{j,k})$  by linear decision rule. Utilize Robust Optimization reformulation techniques.

#### How do we choose $\mathcal{U}$ ?

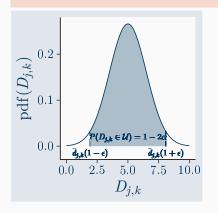

## Assumption: $\mathcal{U}$ is a box uncertainty set

$$\mathcal{U} = \{\tilde{d}_{j,k} | \bar{d}_{j,k} (1 - \epsilon_{j,k}) \le \tilde{d}_{j,k} \le \bar{d}_{j,k} (1 + \epsilon_{j,k})\}$$

#### How do we choose $\mathcal{U}$ ?

## Assumption: $\mathcal{U}$ is a box uncertainty set

$$\mathcal{U} = \{\tilde{d}_{j,k} | \bar{d}_{j,k} (1 - \epsilon_{j,k}) \le \tilde{d}_{j,k} \le \bar{d}_{j,k} (1 + \epsilon_{j,k})\}$$

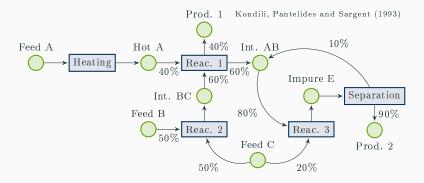

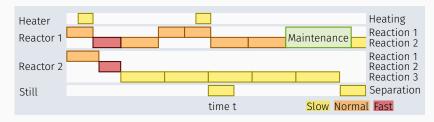

Choose  $\epsilon_{j,k}$  from distribution  $\mathcal{D}_{j,k}$ :

$$\epsilon_{j,k} = 1 - F^{-1}(\alpha)/\bar{d}_{j,k}$$

Size of  $\mathcal{U}$  depends on a single parameter  $\alpha$ !

## Case study: State-Task-Network (Kondili et al., 1993)

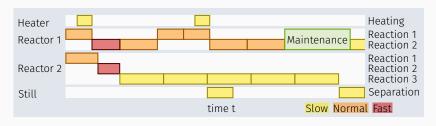

## Case study: State-Task-Network (Kondili et al., 1993)

Biondi, Sand and Harjunkoski (2017) extend the STN to include...

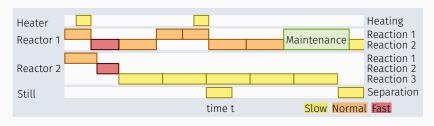

- · ...unit health and maintenance scheduling
- ...integrated scheduling and planning
- $\cdot$  ...multiple operating modes per task

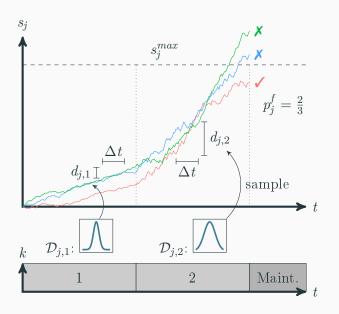

## Case study: State-Task-Network (Kondili et al., 1993)

#### This work...

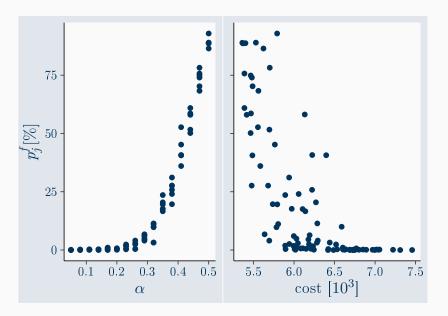

- ...replaces their deterministic health model by the proposed approach based on degradation modelling.
- ...utilizes robust optimization to obtain a solution that is likely to remain feasible.

## Evaluating solution robustness

## The price of robustness

## Choosing $\alpha$ is its own optimization problem

We optimize  $\alpha$  by solving

$$\min_{\alpha} c^*(\alpha) + \sum_{j} p_j^f(\alpha) \cdot c_j^f$$

- $c^*(\alpha)$  is the objective value of a MILP solution given  $\alpha$ .
- $p_j^f(\alpha)$  is the corresponding probability of failure (of unit j).
- $c_i^f$  is the cost of an unexpected failure.

## Choosing $\alpha$ is its own optimization problem

We optimize  $\alpha$  by solving

$$\min_{\alpha} c^*(\alpha) + \sum_{j} p_j^f(\alpha) \cdot c_j^f$$

- $c^*(\alpha)$  is the objective value of a MILP solution given  $\alpha$ .
- $p_j^f(\alpha)$  is the corresponding probability of failure (of unit j).
- $c_i^f$  is the cost of an unexpected failure.

## Idea: Use Bayesian Optimization (BO)

Both  $c^*$  and  $p_j^f$  can be viewed as expensive black box functions. BO is very suitable for this setting (Jones et al., 1998).

## Saving time: a deterministic approximation

## **Assumption**

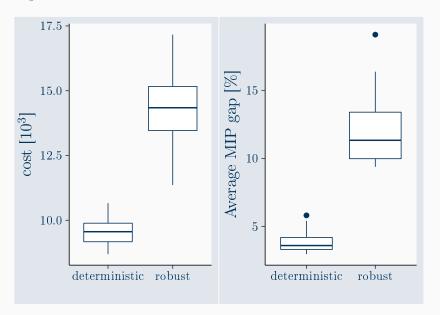

Only the health model depends on  $\tilde{d}_{j,k}$  and  $\tilde{d}_{j,k} \geq 0$ .

Then we can prove that a solution to

$$\begin{aligned} & \underset{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}}{\min} & & \operatorname{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & \text{s.t.} & & \operatorname{process model, maint. model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & s_{j,t} \leq s_{j}^{max} & & \forall t, j \in J \\ & & s_{j,t} = \begin{cases} s_{j,t-1} + \sum\limits_{k \in \mathcal{K}} x_{j,k,t} \cdot \boldsymbol{d}_{j,k}^{max}, & \text{if } m_{j,t} = 0 \\ s_{j}^{0}, & & \text{otherwise} \end{cases} & \forall t, j \in J \end{aligned}$$

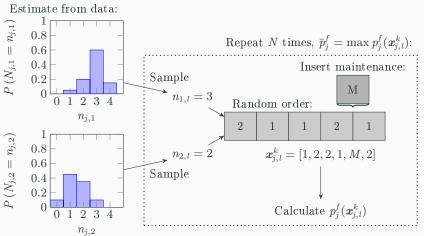

with  $d_{j,k}^{max} = \max_{\mathcal{U}} \tilde{d}_{j,k}$  is also feasible in the robust problem.

## Saving time: a deterministic approximation

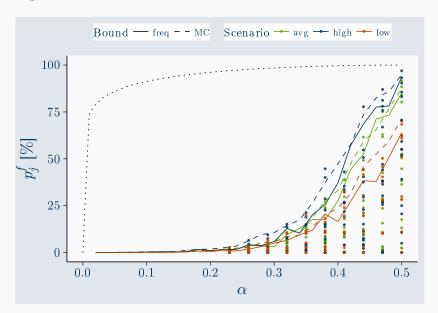

## Saving time: data-driven approximations

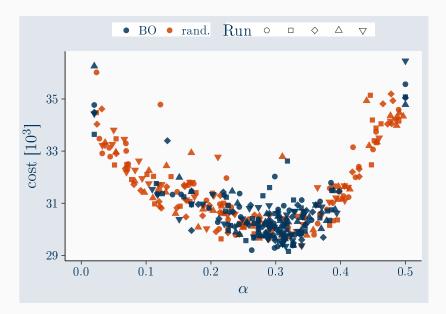

An upper bound on the probability of failure  $p_j^f$  can be estimated from data (using logistic regression).

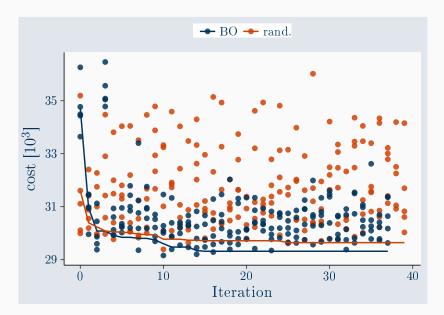

## Saving time: data-driven approximations

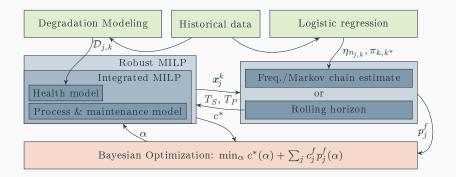

## Bayesian Optimization

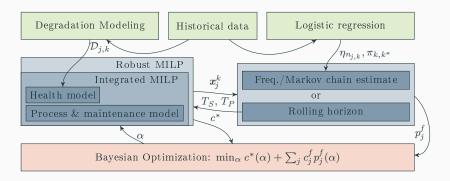

## Bayesian Optimization

#### Conclusion

## Degradation modelling

## Degradation modelling with multiple operating modes

## How does robust optimization work?

#### General idea

- Make constraints hold for all values in  $\mathcal{U}$ :
- $\sum_{j} \tilde{a}_{ij} x_{j} \leq b_{i}, \forall \tilde{a}_{ij} \in \mathcal{U}$

$$\sum_{i} a_{ij} x_j + \text{protection}(\mathcal{U}) \leq b_i$$

· Reformulate semi-infinite constraint:

· How do we choose the right protection level?

## Example: Soyster's method (worst case) [1973]

$$\max_{x_1, x_2} x_1 + x_2$$

s.t. 
$$\tilde{a}_{11}x_1 + \tilde{a}_{12}x_2 \le b_1,$$
  $\forall \tilde{a}_{ii} \in \mathcal{U}$ 

$$\max_{x_1, x_2} x_1 + x_2$$

#### Formulation

# Scheduling

$$M_{j,t}S_{j,0} \leq \tilde{S}_{j,t} \leq S_{j,max} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \qquad \forall t, j \in J, D \in \mathcal{D}$$
  
$$S_{j,t} \geq S_{j,t-\Delta t} + \sum_{i} Z_{j,k,t}D_{j,k,t} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \quad \forall t, j \in J, D \in \mathcal{D}$$

$$S_{j,t} \leq S_{j,t-\Delta t} + \sum_{i} Z_{j,k,t} D_{j,k,t} \qquad \forall t, j \in J, D \in \mathcal{D}$$

$$\begin{aligned} & \underset{S_{j,t} \leq S_{j,max}}{\mathsf{Planning}} \\ & S_{j,t} \leq S_{j,max} & \forall t,j \in J \\ & S_{j,t} \geq S_{j,t-\Delta t} + \sum_{k} N_{j,k,t} D_{j,k,t} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) & \forall t,j \in J \\ & S_{j,t} \leq S_{j,t-\Delta t} + \sum_{k} N_{j,k,t} D_{j,k,t} & \forall t,j \in J \end{aligned}$$

Adjustable robust optimization

#### Affine decision rule

$$S_{j,t} = [S_{j,t}]_0 + \sum_k \sum_{t'=0}^t [S_{j,t}]_{k,t'} D_{j,k,t'}.$$

How do we choose  $\mathcal{U}$ ?

## Choose $\mathcal{U}$ from distribution

- Choose parameter  $\alpha$
- Choose  $D_{min}$  such that  $P(D \le D_{min}) = \alpha$
- Choose  $D_{max}$  such that  $P(D \ge D_{max}) = \alpha$
- $\mathcal{U} = \{D|D_{min} \le D \le D_{max}\}$

## Deriving a robust counterpart

Replace  $D_{j,k}$  by an uncertain parameter  $\tilde{d}_{j,k}$  bounded by a set  $\mathcal{U}$ :

$$\begin{aligned} s_{j,t} &\leq s_j^{max} & \forall t,j \in J \\ s_{j,t} &= \begin{cases} s_{j,t-1} + \sum_{k \in \mathcal{K}} x_{j,k,t} \cdot \tilde{d}_{j,k}, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} & \forall \tilde{d}_{j,k} \in \mathcal{U}, t,j \in J \end{aligned}$$

Reformulate:

$$m_{j,t}s_{j}^{0} \leq s_{j,t} \leq s_{j}^{max} + m_{j,t} \cdot (s_{j}^{0} - s_{j,max}) \qquad \forall t, j \in J, \tilde{d}_{j,k} \in \mathcal{U}$$

$$s_{j,t} \geq s_{j,t-\Delta t} + \sum_{k} x_{j,k,t} \tilde{d}_{j,k} + m_{j,t} \cdot (s_{j}^{0} - s_{j}^{max}) \qquad \forall t, j \in J, \tilde{d}_{j,k} \in \mathcal{U}$$

$$s_{j,t} \leq s_{j,t-\Delta t} + \sum_{k} x_{j,k,t} \tilde{d}_{j,k} \qquad \forall t, j \in J, \tilde{d}_{j,k} \in \mathcal{U},$$

Replace  $s_{j,t}$  by linear decision rule  $s_{j,t} = [s_{j,t}]_0 + \sum_k [s_{j,t}]_k \tilde{d}_{j,k}$ .
