Motivation: Why degradation matters

```
\begin{array}{ccc} \min & \cos t(\boldsymbol{x}, \boldsymbol{m} &) \\ \text{s.t.} & \operatorname{process} \operatorname{model}(\boldsymbol{x}, \boldsymbol{m} &) & \text{(eg. balance equations)} \\ & \operatorname{maintenance} \operatorname{model}(\boldsymbol{x}, \boldsymbol{m} &) & \text{(eg. types of maint.)} \end{array}
```

where \emph{x} are process variables, \emph{m} are maintenance variables

```
\min_{\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}} \quad \operatorname{cost}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h})
s.t. \operatorname{process\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \quad \text{(eg. balance\ equations)}
\operatorname{maintenance\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \quad \text{(eg. types\ of\ maint.)}
\operatorname{health\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}), \quad \text{(eq. prognosis\ model)}
```

where x are process variables, m are maintenance variables, and h are health related variables.

```
\min_{\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}} \quad \operatorname{cost}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h})
s.t. \operatorname{process\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \qquad \text{(eg. balance\ equations)}
\operatorname{maintenance\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \qquad \text{(eg. types\ of\ maint.)}
\operatorname{health\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}), \qquad \text{(eq. prognosis\ model)}
```

where x are process variables, m are maintenance variables, and h are health related variables.

?

```
\begin{array}{ll} \min \limits_{\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}} & \operatorname{cost}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) \\ \text{s.t.} & \operatorname{process\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & \text{(eg. balance\ equations)} \\ & \operatorname{maintenance\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}) & \text{(eg. types\ of\ maint.)} \\ & \operatorname{health\ model}(\boldsymbol{x},\boldsymbol{m},\boldsymbol{h}), & \text{(eq. prognosis\ model)} \end{array}
```

where x are process variables, m are maintenance variables, and h are health related variables.

Idea

Combine process level MI(N)LP scheduling & planning with more sophisticated (stochastic) degradation modelling and robust optimization.

The degradation signal $s^{meas}(t)$ is often modelled by a stochastic process:

$$S(t) = \{S_t : t \in T\},\$$

where S_t is a random variable.

3

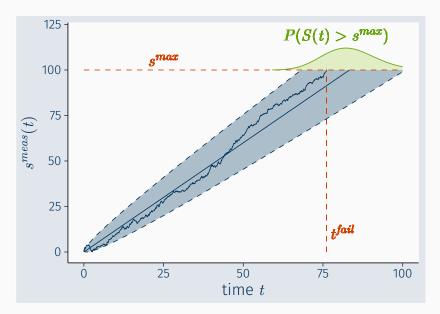

The degradation signal $s^{meas}(t)$ is often modelled by a stochastic process:

$$S(t) = \{S_t : t \in T\},\$$

where S_t is a random variable.

Often used: Lévy type processes

- Independent increments: $S_{t_2}-S_{t_1},...,S_{t_n}-S_{t_{n-1}}$ are independent for any $0 < t_1 < t_2 < ... < t_n < \infty$
- Stationary increments: $S_t S_s$ and S_{t-s} have the same distribution for any s < t
- Continuity in probability: $\lim_{h\to 0} P(|S_{t+h}-S_t|>\epsilon)=0$ for any $\epsilon>0$, $t\geq 0$.

A health model based on Lévy processes

Assumption

The health of each unit j can be described by a Lévy process $S_j(t)$ with increments $S_{j,t} - S_{j,t-\Delta t} = D_j \sim \mathcal{D}_j(\Theta, \Delta t)$.

A health model based on Lévy processes

Assumption

The health of each unit j can be described by a Lévy process $S_j(t)$ with increments $S_{j,t} - S_{j,t-\Delta t} = D_j \sim \mathcal{D}_j(\boldsymbol{\Theta}, \boldsymbol{x}, \Delta t)$.

$$\begin{aligned} & \underset{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}}{\text{min}} & & \operatorname{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & \text{s.t.} & & \operatorname{process\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & \operatorname{maintenance\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & S_{j,t} \leq s_j^{max} & & \forall t, j \in J \\ & & S_{j,t} = \begin{cases} S_{j,t-1} + D_j, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} & \forall t, j \in J \end{aligned}$$

where $m_{j,t} = 1$ if maintenance is performed on unit j at time t.

Accounting for effects of process variables

Assumption [Liao & Tian 2013]

All relevant operating variables are piecewise constant – i.e. the process has a set of discrete operating modes $k \in K$.

$$\begin{aligned} & \underset{x,m,h}{\min} & & \operatorname{cost}(x,m,h) \\ & \text{s.t.} & & \operatorname{process\ model}(x,m,h) \\ & & & \operatorname{maintenance\ model}(x,m,h) \\ & & & S_{j,t} \leq s_{j}^{max} & & \forall t,j \in J \\ & & & \\ & S_{j,t} = \begin{cases} S_{j,t-1} + & D_{j} \ , & \text{if} \ m_{j,t} = 0 \\ s_{j}^{0}, & \text{otherwise} \end{cases} & \forall t,j \in J \end{aligned}$$

where $x_{j,k,t} = 1$ if unit j operates in mode k at time t.

Accounting for effects of process variables

Assumption [Liao & Tian 2013]

All relevant operating variables are piecewise constant – i.e. the process has a set of discrete operating modes $k \in K$.

$$\begin{aligned} & \min_{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}} & & \operatorname{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & \text{s.t.} & & \operatorname{process\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & \operatorname{maintenance\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & S_{j,t} \leq s_j^{max} & & \forall t, j \in J \\ & & & S_{j,t} = \begin{cases} S_{j,t-1} + \sum\limits_{\boldsymbol{k} \in \mathcal{K}} \boldsymbol{x}_{j,\boldsymbol{k},t} \cdot D_{j,\boldsymbol{k}}, & \text{if } m_{j,t} = 0 \\ s_j^0, & & \text{otherwise} \end{cases} & \forall t, j \in J \end{aligned}$$

where $x_{j,k,t} = 1$ if unit j operates in mode k at time t.

Deriving a robust counterpart [Lappas & Gounaris 2016]

Replace random variables $D_{j,k}$ and $S_{j,t}$ by uncertain parameter $\tilde{d}_{j,k} \in \mathcal{U}$ and second stage variable $s_{j,t}\left(\tilde{d}_{j,k}\right)$.

$$\begin{aligned} & \underset{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}}{\min} & & \operatorname{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & \text{s.t.} & & \operatorname{process\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & \text{maintenance\ model}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}) \\ & & & & \boldsymbol{s_{j,t}} \left(\tilde{\boldsymbol{d}_{j,k}}\right) \leq s_j^{max} & & \forall t, j \in J \\ & & & \boldsymbol{s_{j,t}} = \begin{cases} \boldsymbol{s_{j,t-1}} + \sum\limits_{k \in \mathcal{K}} x_{j,k,t} \cdot \tilde{\boldsymbol{d}_{j,k}}, & \text{if } m_{j,t} = 0 \\ s_j^0, & & \text{otherwise} \end{cases} & \forall t, j \in J \end{aligned}$$

 $orall ilde{d}_{j,k} \in \mathcal{U}$. Approximate $s_{j,t}\left(ilde{d}_{j,k}
ight)$ by linear decision rule.

How do we choose \mathcal{U} ?

Assumption: \mathcal{U} is a box uncertainty set

$$\mathcal{U} = \{\tilde{d}_{j,k} | \bar{d}_{j,k} (1 - \epsilon_{j,k}) \le \tilde{d}_{j,k} \le \bar{d}_{j,k} (1 + \epsilon_{j,k})\}$$

How do we choose \mathcal{U} ?

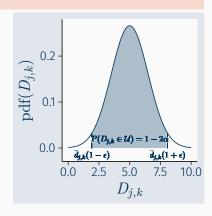

Assumption: \mathcal{U} is a box uncertainty set

$$\mathcal{U} = \{\tilde{d}_{j,k} | \bar{d}_{j,k} (1 - \epsilon_{j,k}) \le \tilde{d}_{j,k} \le \bar{d}_{j,k} (1 + \epsilon_{j,k})\}$$

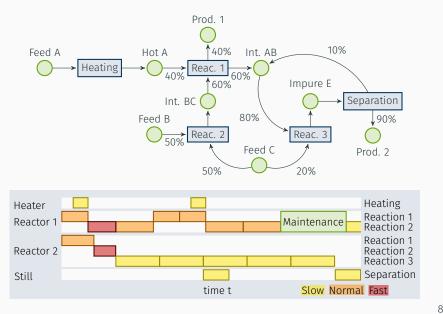

Choose $\epsilon_{j,k}$ from distribution $\mathcal{D}_{j,k}$:

$$\epsilon_{j,k} = 1 - F^{-1}(\alpha)/\bar{d}_{j,k}$$

Size of $\mathcal U$ depends on a single parameter $\alpha!$

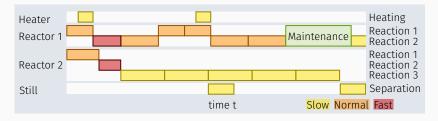

Case study: State-Task-Network [Kondili et al. 1993]

Case study: State-Task-Network [Kondili et al. 1993]

Biondi et al. (2017) extend the STN to include...

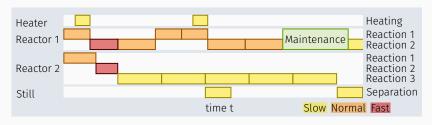

- · ...unit health and maintenance scheduling
- · ...integrated scheduling and planning
- ...multiple operating modes per task

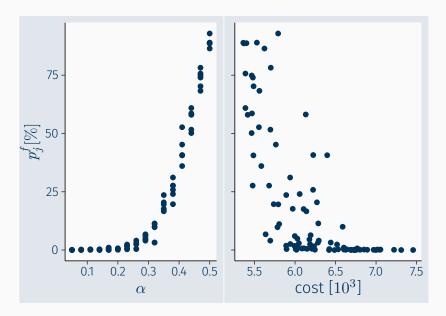

Case study: State-Task-Network [Kondili et al. 1993]

This work...

- ...replaces their deterministic health model by the proposed degradation modeling based model.
- ...utilizes robust optimization to obtain a solution that is likely to remain feasible.

The price of robustness

Choosing α is its own optimization problem

We optimize α by solving

$$\min_{\alpha} c^*(\alpha) + \sum_{j} p_j^f(\alpha) \cdot c_j^f$$

- $c^*(\alpha)$ is the objective value of a MILP solution given α .
- $p_j^f(\alpha)$ is the corresponding probability of failure (of unit j).
- · c_j^f is the cost of an unexpected failure.

Choosing α is its own optimization problem

We optimize α by solving

$$\min_{\alpha} c^*(\alpha) + \sum_{j} p_j^f(\alpha) \cdot c_j^f$$

- $c^*(\alpha)$ is the objective value of a MILP solution given α .
- $p_j^f(\alpha)$ is the corresponding probability of failure (of unit j).
- · c_j^f is the cost of an unexpected failure.

Idea: Use Bayesian Optimization (BO)

Both c^* and p_j^f can be viewed as expensive black box functions. BO is very suitable for this setting.

Saving time: a deterministic approximation

Assumption

Only the health model depends on $\tilde{d}_{j,k}$ and $\tilde{d}_{j,k} \geq 0$.

Then we can prove that a solution to

$$\min_{\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h}} \; \mathsf{cost}(\boldsymbol{x}, \boldsymbol{m}, \boldsymbol{h})$$

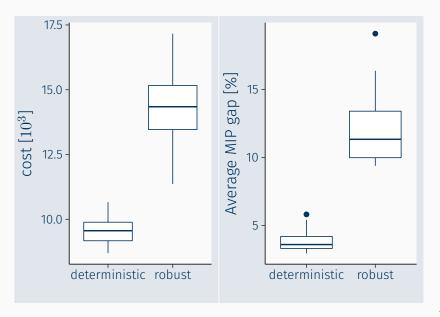

s.t. process model, maint. $model(x, m, \frac{h}{h})$

$$s_{j,t} \leq s_j^{max} \qquad \forall t, j \in J$$

$$s_{j,t} = \begin{cases} s_{j,t-1} + \sum_{k \in \mathcal{K}} x_{j,k,t} \cdot d_{j,k}^{max}, & \text{if } m_{j,t} = 0 \\ s_j^0, & \text{otherwise} \end{cases} \quad \forall t, j \in J$$

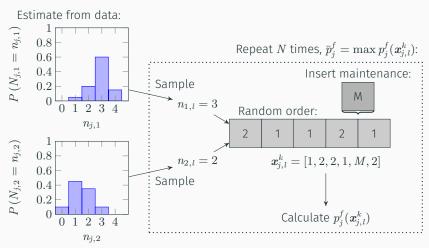

with $d_{j,k}^{max} = \max_{\mathcal{U}} \tilde{d}_{j,k}$ is also feasible in the robust problem.

Saving time: a deterministic approximation

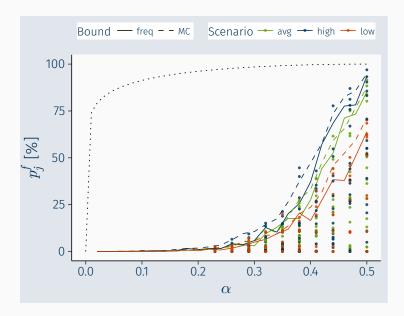

Saving time: data-driven approximations

An upper bound on the probability of failure p_j^f can be estimated from data (using logistic regression).

Outlook

Optimizing $\boldsymbol{\alpha}$

$$\min_{\alpha} c^*(\alpha) + \sum_{j} p_j^f(\alpha) \cdot c_j^f$$

Degradation modelling with multiple operating modes

How does robust optimization work?

General idea

- Make constraints hold for all values in ${\cal U}$:

$$\sum_{j} \tilde{a}_{ij} x_j \leq b_i, \forall \tilde{a}_{ij} \in \mathcal{U}$$

· Reformulate semi-infinite constraint:

$$\sum_{j} a_{ij}x_{j} + \text{protection}(\mathcal{U}) \leq b_{i}$$

• How do we choose the right protection level?

Example: Soyster's method (worst case) [1973]

$$\max_{x_1, x_2} x_1 + x_2$$

s.t.
$$\tilde{a}_{11}x_1 + \tilde{a}_{12}x_2 \leq b_1$$
,

$$\forall \tilde{a}_{ij} \in \mathcal{U}$$

$$\max_{x_1, x_2} x_1 + x_2$$

Formulation

$$M_{j,t}S_{j,0} \leq \breve{S}_{j,t} \leq S_{j,max} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \qquad \forall t, j \in J, D \in \mathcal{D}$$
$$S_{j,t} \geq S_{j,t-\Delta t} + \sum_{k} Z_{j,k,t}D_{j,k,t} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \quad \forall t, j \in J, D \in \mathcal{D}$$

$$S_{j,t} \le S_{j,t-\Delta t} + \sum_{k} Z_{j,k,t} D_{j,k,t}$$

$$\forall t, j \in J, D \in \mathcal{D}$$

Planning

$$S_{j,t} \le S_{j,max} \qquad \forall t, j \in J$$

$$S_{j,t} \ge S_{j,t-\Delta t} + \sum_{k} N_{j,k,t} D_{j,k,t} + M_{j,t} \cdot (S_{j,0} - S_{j,max}) \quad \forall t, j \in J$$

$$S_{j,t} \le S_{j,t-\Delta t} + \sum_{t} N_{j,k,t} D_{j,k,t}$$

$$\forall t, j \in J$$

Adjustable robust optimization

Affine decision rule

$$S_{j,t} = [S_{j,t}]_0 + \sum_k \sum_{t'=0}^t [S_{j,t}]_{k,t'} D_{j,k,t'}. \tag{1}$$

How do we choose \mathcal{U} ?

Choose \mathcal{U} from distribution

- \cdot Choose parameter lpha
- Choose D_{min} such that $P(D \le D_{min}) = \alpha$
- Choose D_{max} such that $P(D \ge D_{max}) = \alpha$
- $U = \{D|D_{min} \le D \le D_{max}\}$

Robust optimization:deriving a robust counterpart [lappas & gounaris 2016]

Replace $D_{i,k}$ by an uncertain parameter $\tilde{d}_{i,k}$ bounded by a set

$$\begin{aligned} &\mathcal{U}:\\ s_{j,t} \leq s_{j}^{max} & \forall t,j \in J \\ s_{j,t} = \begin{cases} s_{j,t-1} + \sum_{k \in \mathcal{K}} x_{j,k,t} \cdot \tilde{d}_{j,k}, & \text{if } m_{j,t} = 0 \\ s_{j}^{0}, & \text{otherwise} \end{cases} & \forall \tilde{d}_{j,k} \in \mathcal{U}, t,j \in J \\ \end{aligned}$$
 Reformulate:
$$m_{j,t}s_{j}^{s} \leq s_{j,t} \leq s_{j}^{max} + m_{j,t} \cdot (s_{j}^{0} - s_{j,max}) & \forall t,j \in J, \tilde{d}_{j,k} \in \mathcal{U} \\ s_{j,t} \geq s_{j,t-\Delta t} + \sum_{k} x_{j,k,t} \tilde{d}_{j,k} + m_{j,t} \cdot (s_{j}^{0} - s_{j}^{max}) & \forall t,j \in J, \tilde{d}_{j,k} \in \mathcal{U} \\ s_{j,t} \leq s_{j,t-\Delta t} + \sum_{k} x_{j,k,t} \tilde{d}_{j,k} & \forall t,j \in J, \tilde{d}_{j,k} \in \mathcal{U}, \end{aligned}$$

Replace $s_{j,t}$ by linear decision rule $s_{j,t} = [s_{j,t}]_0 + \sum_k [s_{j,t}]_k \tilde{d}_{j,k}$.
